### Contents of this file

Tables S1 and S2

Additional MATLAB codes to calculate plunge-pool erosion attached separately

- `example_pool_erosion.m`: Example script to run plunge-pool erosion codes
- `pool_erosion_simple_fct.m`: Main script to calculate plunge-pool erosion
- `pool_erosion_fct_public.m`: Sub-script embedded within the plunge-pool erosion code
- `Qsc_pool_public.m`: Sub-script embedded within the plunge-pool erosion code
- `c_from_Qs_fct.m`: Sub-script embedded within the plunge-pool erosion code
- `readme.txt`: Additional information and disclaimer for codes

**Introduction:** This supporting information contains two tables and MATLAB codes. Table S1 contains data for natural waterfall plunge pools surveyed by *Scheingross and Lamb [2016]*, including data from the Fox Creek reference site, which we use to estimate maximum possible plunge-pool radii and to evaluate assumptions that particles can detach from fluid flow to impact exposed bedrock in plunge pools. Table S2 contains parameters used in the *Scheingross et al. [2017]* plunge-pool erosion experiments which we use to calculate model predictions of plunge pool erosion. The MATLAB codes can be used to calculate plunge-pool vertical and lateral erosion following the theory developed here.

**Table S1.** Compilation of natural plunge pools (attached)

**Table S2.** Summary of parameters for waterfall plunge-pool erosion experiments (attached)

<sup>a</sup> Data for natural plunge pools compiled by Scheingross and Lamb [2016]. Pool depth ( $h_{pool}$ ) refers to the vertical distance from the downstream plunge-pool lip to the pool floor (i.e.,  $h_{pool} = z_{lip} - z_{sed}$ ) which was typically sediment but for some pools the bedrock floor was exposed (as indicated in the "pool floor" column where "sed" and "br" indicate a sediment versus bedrock floor, respectively, and "?" indicates no distinction was made). Waterfalls were surveyed at low flow when pools were often partially filled with sediment, and pool depths should be greater when the bedrock floor is exposed and vertical erosion occurs. The radial jet half width at  $b_{lat}(\delta)$  was calculated with Eq. (29), and we interpret the generally large values of  $h_{pool}/b_{lat}(\delta)$  to suggest our assumption that falling grains impact the pool floor without significant deflection from radial jets likely holds in natural pools. Similarly,  $l_{e\_fold}/b_{lat}(r_{pool})$  represents the ability of particles within the radial wall jet to detach from the flow and impact the pool wall, and was calculated assuming a drag coefficient of 1, where  $l_{e\_fold}$  is an e-folding length scale for particles slowing due to drag.  $r_{max}/r_{crit}$  is the ratio of maximum plunge-pool radius ( $r_{max}$ , set by the sediment transport capacity of the pool) relative to the critical radius needed for caprock failure via undercutting ( $r_{crit}$ ). Additional variables:  $D$  - estimated median grain size in the river reach adjacent to the plunge pool,  $r_{pool}$  - field-measured plunge-pool radius,  $H_{drop}$  - field-measured waterfall drop height,  $Q_{2yr}$  - two-year recurrence interval water discharge.

<sup>b</sup> This waterfall occurs downstream of the Fox Creek knickzone and was not included in the Fox Creek reference site calculations.

**Table S2.** Summary of parameters for waterfall plunge-pool erosion experiments<sup>a</sup>

Experiment ID	Water discharge (l/s)	Waterfall drop height (m)	Grain diameter (mm)	Sediment flux (g/s)	Flow depth at brink (cm)	Upstream flume slope (deg)	Downstream flume slope (deg)	Total run time (hr)
Exp1	0.58	0.42	2.4	9	1.3	2	10	113
Exp2	0.58	0.53	7	9 - 45	1.3	2	14.5	51

<sup>a</sup> All experiments used a commercially available, closed-cell polyurethane foam bedrock simulant (<http://www.precisionboard.com>), with 0.32 MPa tensile strength. In both experiments the upstream flume is 9.6 cm wide, 2.06 m long, is tilted to ~2 degrees, and has a fixed bed of 2.4 mm sub-rounded quartz grains. The downstream flume is 24 cm wide and 80 cm long, and in which we fixed a polyurethane foam block (~18 cm wide by 27 cm long).
